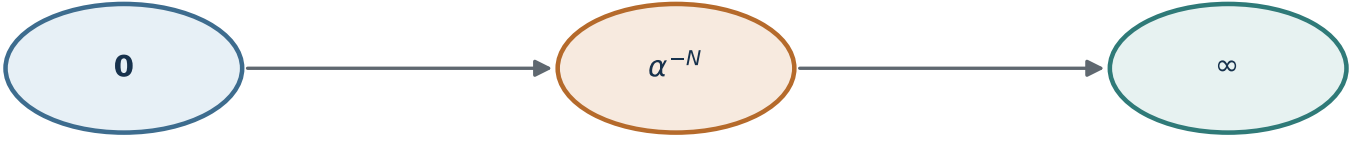
Fuchsian exponent packet after binomial multisection

$E_0 = \{0, 1/N, \ldots, (N-1)/N\}$ $E_{\alpha^{-N}} = \{0, 1, \ldots, N-2, -\lambda\}$ $E_\infty = \{(\lambda + j + r)/N\}$



local eigenvalue ratios are torsion when lambda is rational

The N rotated source singularities alias to one finite packet singularity.
Finite local eigenvalue torsion does not imply a finite global monodromy group.
